AGENTIC COMMERCE.

Why DLT is a key building block for tomorrow's payments.

PIOTR "PETER" SWIERZY · CO-FOUNDER, BLOCKYDEVS

**Right now, somewhere,
an agent just bought
something on your behalf.**

No human approved it. No receipt landed in an inbox.
No one will audit it before the books close.

What is Agentic Commerce?

DEFINITION

Machines acting as autonomous economic agents — discovering goods and services, negotiating terms, executing payments, and settling obligations on behalf of a human, an organization, or another machine.

WHAT IT IS NOT

- An “AI shopping assistant” that recommends and a human still pays.
- A chatbot booking flights inside one walled garden.
- A wrapper on a credit card.
It is a new substrate, not a UI skin.

Agentic commerce is a spectrum of agency.

AI shopping isn't excluded — it's the on-ramp. The talk is about the whole axis.

01 · SUGGESTIVE

**AI recommends.
Human decides and
pays.**

Today's AI shopping assistants,
Copilot-style suggestions, comparison
agents.

02 · DELEGATED

**Agent executes within
a human-set policy.**

Mandate tokens, AP2 Intent + Cart,
agent-issued cards with spend limits.

03 · AUTONOMOUS

**Agent-to-agent.
No human in the loop
per transaction.**

Machine-to-machine procurement,
per-API-call settlement, agent
marketplaces.

Not hype. The numbers — scoped to autonomous agents.

Not “AI features inside software.” Agents executing decisions and transactions.

15%

of day-to-day work decisions
made autonomously by 2028.

From 0% in 2024.

GARTNER · 2025

\$15T

in B2B purchasing intermediated
by AI agents by 2028.

90% of B2B buying flows.

GARTNER · 2025

\$3–5T

consumer commerce
orchestrated by AI agents by
2030.

Agents that transact, not assist.

MCKINSEY · 2025

1B+

deployed AI agents executing
217B actions/day by 2029.

~40× the 2025 agent base.

IDC FUTUREScape · 2026

Five capabilities an agent needs to transact.

Strip any one out and the system either won't work, won't scale, or won't be deployable.

01	IDENTITY	Who is the agent? Who does it act for?
02	INTENT / MANDATE	What is it authorized to do, and within what limits?
03	PAYMENT	How does it transfer value at machine speed?
04	SETTLEMENT	How does the value actually move and clear?
05	AUDIT	Can you prove later what it did, in what order, and on whose authority?

01 Identity.

WHAT IT IS

A cryptographic name the agent can prove, that's portable across services and persistent over time. Not a session cookie, not an API key.

WHY IT'S REQUIRED

Counterparties need to know who they're dealing with before they accept signed mandates, signed payments, or signed audit entries. Identity is the prerequisite for everything signable.

WHAT BREAKS WITHOUT IT

Zero accountability. Sybil attacks. No reputation accrual. No way to revoke a compromised agent. No legal recourse when something goes wrong.

IN PRACTICE

→ W3C DIDs and Verifiable Credentials • ERC-8004 registries (300k+ agents registered since Jan 2026) • Hedera account IDs as agent identities

02 Intent / Mandate.

WHAT IT IS

A cryptographically signed instruction that bounds what the agent is allowed to do — amount, merchants, time window, purpose — verifiable by any counterparty.

WHY IT'S REQUIRED

An agent that can buy anything is a liability. Mandates turn “trust the agent” into “trust the signature on a specific authorization,” the way a power of attorney works for humans.

WHAT BREAKS WITHOUT IT

No way to prove the principal authorized a transaction. No way to constrain agents in regulated industries. No defensible audit story for compliance.

IN PRACTICE

→ Google AP2: Intent / Cart / Payment mandates (signed VDCs) • Mastercard Agentic Tokens (agent-bound EMV credentials) • Visa Trusted Agent Protocol (RFC 9421) • Stripe / OpenAI ACP: Shared Payment Token (live in ChatGPT)

03/04 **Payment & Settlement.**

Two distinct layers, often conflated. The trigger fires the transaction. The rails actually move the value.

THE TRIGGER

How does the agent ask to pay?

HTTP-native challenge/response. A server returns 402 with payment requirements; the agent signs and replays.

Rail-agnostic — dispatches onto card rails, stablecoin rails, or anything that can settle a signed authorization.

x402 · AP2 · ACP

THE RAILS

How does the value actually move?

Card networks (Visa/MC tokenized credentials, agent-issued cards). Stablecoin rails (USDC on Base/Solana/Hedera). Bank rails (SEPA, instant schemes).

Different floors, different finality, different chargeback rights. The right rail depends on the transaction, not the protocol.

Visa · MC · Stripe · USDC · HBAR

05 Audit.

Every agent action signed, ordered, and committed to a tamper-evident log. Not the agent's own database.

REGULATOR

**BaFin. GDPR. MiCA.
EU AI Act.**

Funds or high-risk decisions:
supervisors need a reconstructable
history — not a vendor's word. EU AI
Act Article 12 makes logging
mandatory.

CUSTOMER

Dispute resolution.

“The agent did X without permission.”
Either you can prove the chain of
authorization or you absorb the loss.

OPERATOR

Incident forensics.

When a fleet of agents misbehaves at
3am, you need to replay exactly what
each one did, in what order, on whose
authority.

KEY INSIGHT → An app log on the agent's own infra is not an audit trail — it's a story the agent tells about itself.

The protocol stack — every layer, named.

Industry convergence on these layers is the strongest signal we have. None of it is theoretical.

COMMERCE discovery, cart, checkout	ACP (OpenAI · Stripe) · UCP (Google)
COMMUNICATION agent ↔ agent + agent ↔ tool	A2A (Linux Foundation) · MCP (Anthropic)
PAYMENT TRIGGER how the request to pay is made	x402 (Coinbase) · AP2 (Google) · Stripe MPP
SETTLEMENT where the value actually clears	Networks: Visa · Mastercard · Stripe · Stablecoin: USDC on Base/Solana/Hedera
AUDIT tamper-evident agent history	Hedera HCS · EVM event logs · TEE attestation (EQTY Lab)
IDENTITY who the agent is, portable	DIDs · VCs · ERC-8004 registries · HCS-10 OpenConvAI
LEGAL / DISPUTES (new) terms discovery + ATR hash + arbitration	LCP (AAA-ICDR + Integra Ledger, launched Jun 2026)

Coinbase · Cloudflare · Google · OpenAI · Visa · Mastercard · Stripe · AWS · Anthropic · Circle · Hedera

The ad-funded web is structurally breaking.

AI mediates content. Impressions disappear. The model that funded the open web for 25 years no longer fits the new traffic shape.

~13,500:1

ClaudeBot crawl-to-referral ratio (Apr 2026).

Googlebot baseline ~5:1.
OpenAI ~1,250:1.

CLOUDFLARE RADAR

15% → 8%

Click-through without / with Google AI Overviews.

Halved. Only 1% click the AI's own cited sources.

PEW RESEARCH · 2025

–33%

Global news referrals from Google search, YoY.

–38% US, –17% Europe.

PRESS GAZETTE · 2025

15×

Growth in user-driven AI bot crawls in 2025.

1 AI bot visit per 31 human visits, up from 1:50.

CLOUDFLARE · TOLLBIT

ALREADY SHIPPING

Cloudflare Pay Per Crawl (Jul 2025) — publishers set a per-request price; crawlers hit HTTP 402; interoperates with x402.

x402 — HTTP-native payments for agents.

Coinbase, May 2025. v2 Dec 2025. Foundation governance with Google, Visa, AWS, Cloudflare, Anthropic, Circle.

WHY IT MATTERS

Resource servers run no chain, hold no gas, accept no chargebacks. The facilitator settles; the agent's wallet does the lifting.

The economic floor: why card rails can't reach the long tail.

An entire economic tier — per-API-call, per-token, per-fetch — is structurally impossible on \$0.30-floor rails.

RAIL	PER-TX COST	FINALITY	REVERSIBLE?
Card (Visa / MC)	\$0.30 + 2.9%	T+1 settlement	Yes (chargebacks)
Ethereum L1	\$0.02–0.1 transfer	~13 min economic	No (probabilistic)
Base L2	~\$0.02 median	2s soft / 7-day canonical	No
Solana	~\$0.0005–0.0018	0.4s soft / ~13s final	No (re-orgs rare)
Hedera HBAR	\$0.0001 fixed (USD)	3–5s, aBFT final	No (deterministic)
Hedera HCS message	\$0.0008 fixed (USD)	3–5s, aBFT final	No (deterministic)

THE AGENT-GRADE ARGUMENT

Hedera fees are denominated in USD and pinned by the Council. An agent quoting a 10,000-call workflow knows the cost is a compile-time constant — independent of HBAR price action and immune to gas-spike risk. EVM rails cannot do that.

HCS — a purpose-built ledger for agent telemetry.

Not a smart-contract chain. A native sequencer that gives any payload a consensus timestamp, sequence number, and running hash.

\$0.0008	PER MESSAGE USD-pinned. ~1M writes ≈ \$800.
10,000+	TPS Throughput on HCS / HTS.
3–5s	FINALITY aBFT, deterministic.

CASE STUDY

EQTY Lab × NVIDIA × Accenture

TEE-attested AI inference. Each AI operation generates a cryptographic certificate anchored to HCS — a public, tamper-evident trail of what model ran, on what hardware, with what inputs, in what order.

Extended to “Verifiable Governance for AI Agents” for the public sector.

How an agent action becomes a tamper-evident audit entry.

KEY PROPERTY → the running hash makes the topic tamper-evident. Reorder a single message and every subsequent hash diverges.

Hedera AI Studio — the PoC starting point.

All four agent primitives shipped, scriptable from TypeScript, working in a day.

01	Hedera Agent Kit v4	TypeScript SDK. Accounts, HTS, HCS, EVM, scheduled tx, plugins.
02	Policies & Audit Trails	Create immutable audit trails, and enforce strict business logic and security policies.
03	MCP Server	Hedera primitives exposed to MCP-compatible clients (Claude, Cursor).
04	Framework adapters	LangChain v1 + Classic, Vercel AI SDK, ElizaOS.

TAKEAWAYS

- 01. Agentic commerce is a structural shift, not a hype cycle — the economic floor argument decides where it has to land.
- 02. DLT earns its place on three specific problems: sub-cent micropayments, deterministic settlement for machines, tamper-evident audit.
- 03. The infrastructure already ships. You can build a PoC this month on Hedera AI Studio.

Thank you!
